

Variation in earthquake surface rupture characteristics across intraplate Australia

As they relate to fault displacement hazard assessment

FDHA - intraplate style

- Fault displacement hazard requires recurrence
- How should the term 'recurrence' be understood in the intraplate setting?
- periodic
- episodic
- random
- no recurrence, or 'one-off'

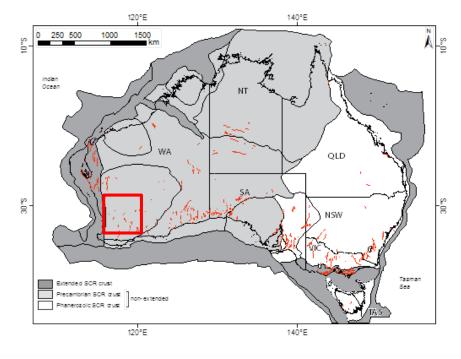

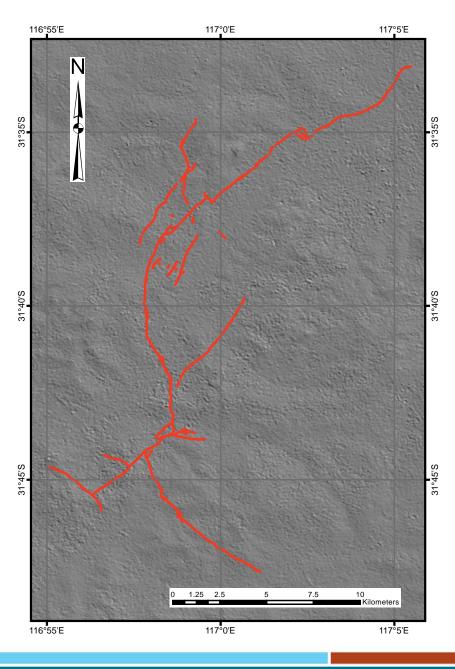

GEOSCIENCE AUSTRALIA

Cratonic domains

- short, complex scarps
- isolated
- little relief
- erosion rates 1-5 m/Myr

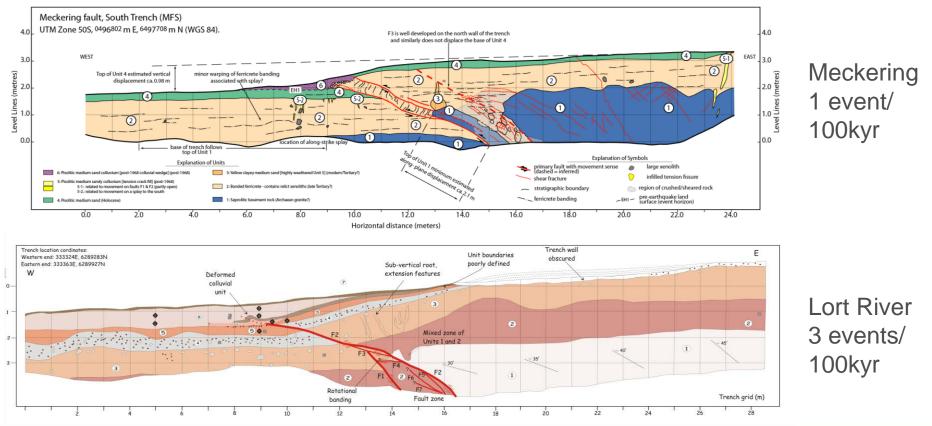

GEOSCIENCE AUSTRALIA

Cratonic Fault Characteristics

- 1-3 or 4 events in the last 100 kyr
- slip rate in last 100kyr ~0.01-0.03 mm/yr (10-30m/Myr)
- long term slip rate <0.001 mm/yr (<1m/Myr, so relief transient)

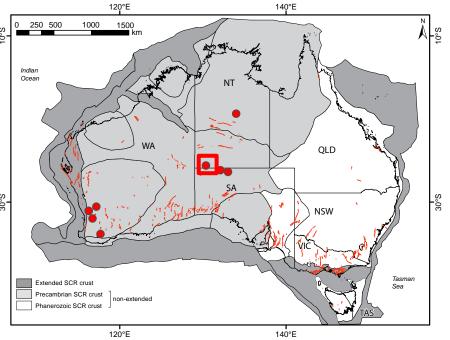

GEOSCIENCE AUSTRALIA

One-off ruptures in the cratonic domains?

- All historic surface ruptures occurred in unanticipated locations
- All in Cratonic Domains

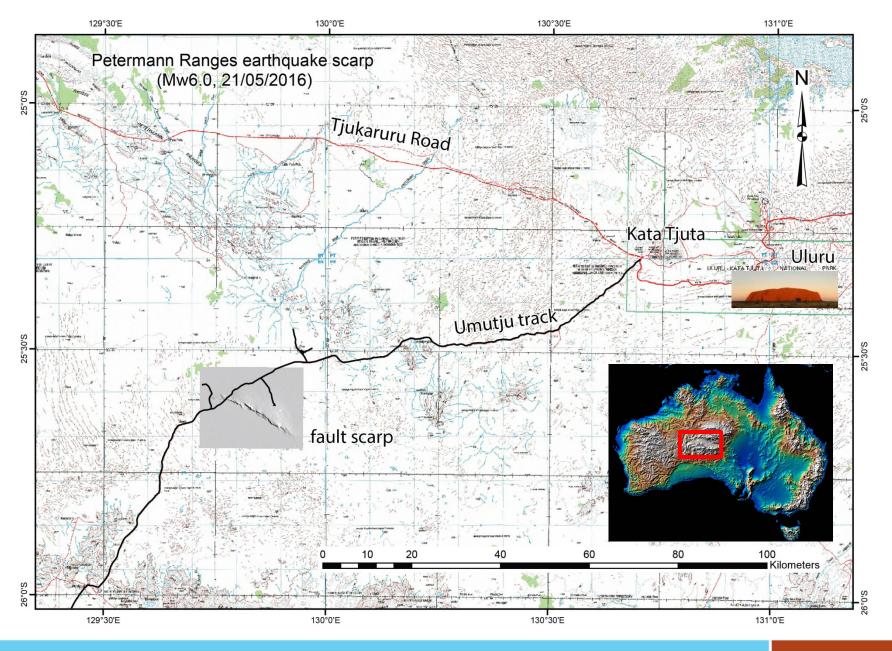

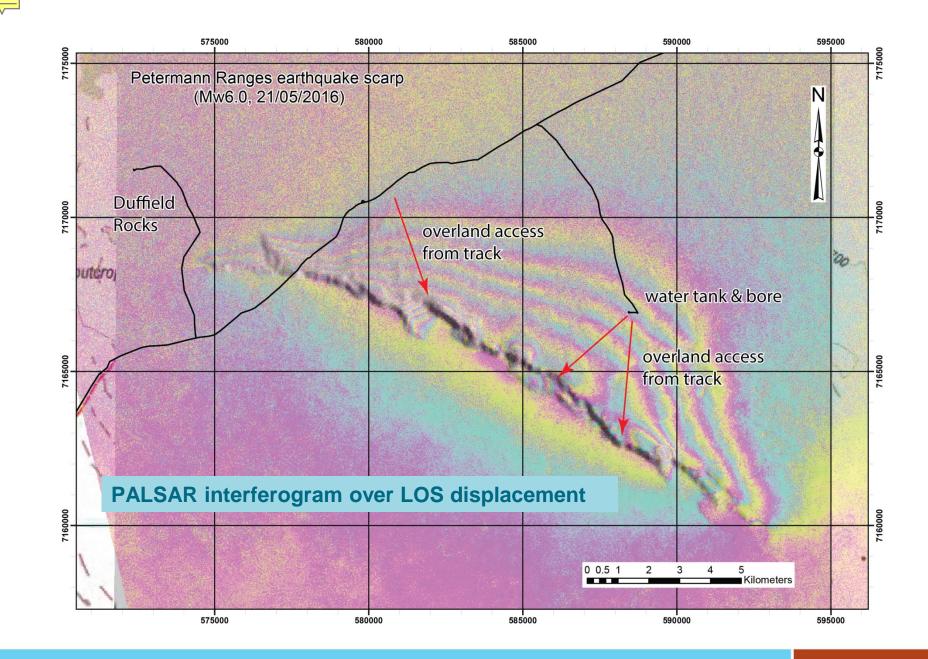

May 21st 2016 Mw6.1 Petermann Ranges earthquake scarp

GEOSCIENCE AUSTRALIA

GEOSCIENCE AUSTRALIA

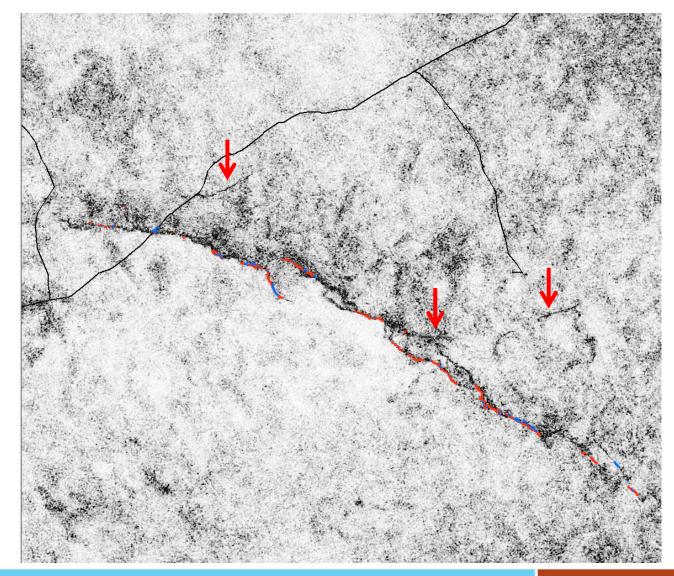

INSAR filtered coherence image

Shows exactly where displacement hazard was

Not only where we mapped a scarp

Recurrence? Note bedrock in footwall

GEOSCIENCE AUSTRALIA

© Commonwealth of Australia (Geoscience Australia) 2016

Bedrock in the footwall = no recurrence

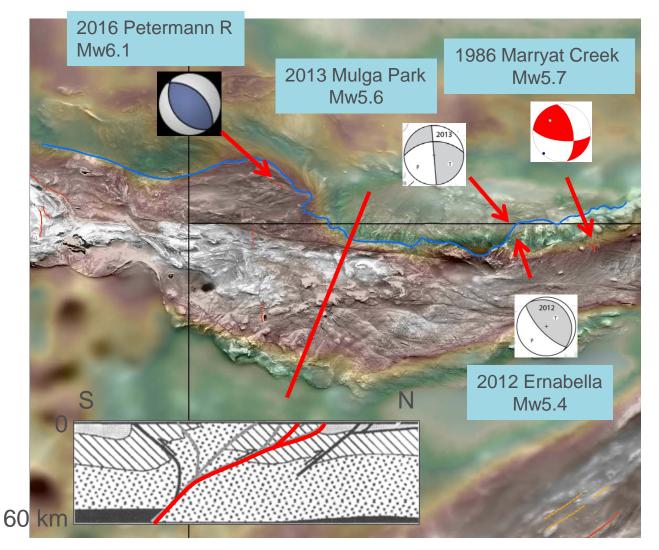

GEOSCIENCE AUSTRALIA

© Commonwealth of Australia (Geoscience Australia) 2016

Spatially distributed recurrence?

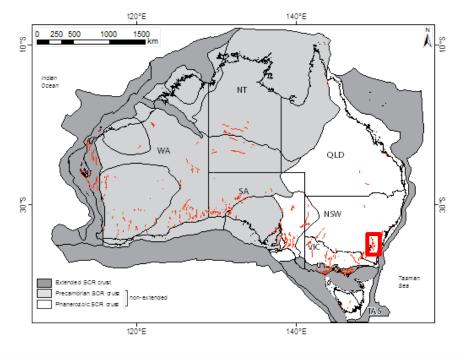

Events localised to the Woodroffe Thrust, a major Proterozoic to Cambrian intraplate fault system

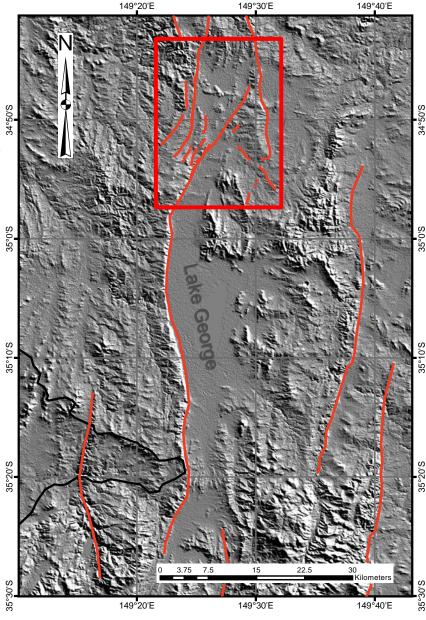

© Commonwealth of Australia (Geoscience Australia) 2016

- no historic surface ruptures
- longer, linear, connected scarps
- significant relief = recurrence
- erosion rates 30-50 m/Myr

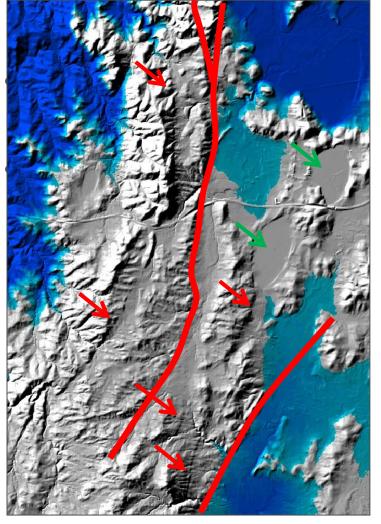

GEOSCIENCE AUSTRALIA

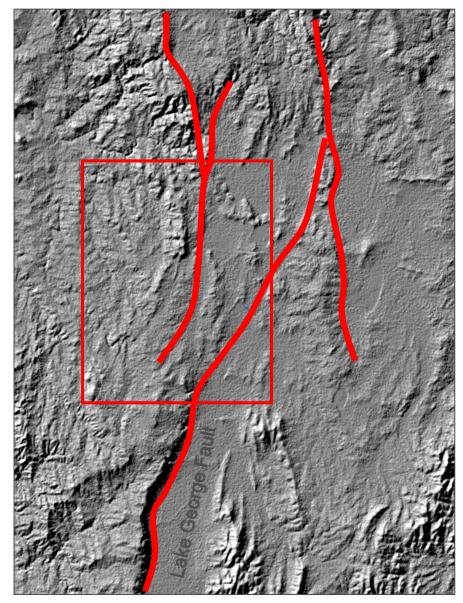

SRTM

Complex linkages

LiDaR

GEOSCIENCE AUSTRALIA

Recurrence in the noncratonic domains?

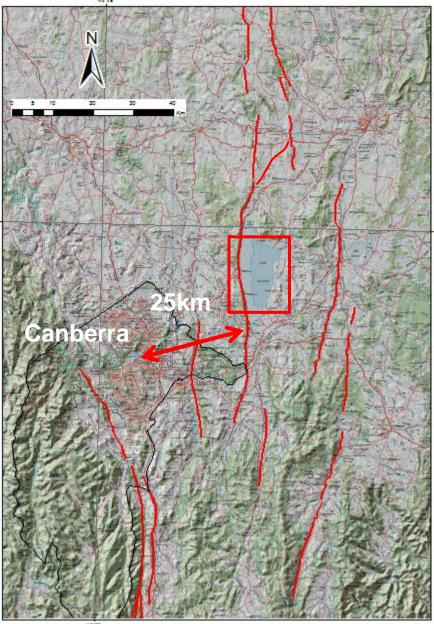

The Lake George fault scarp and basin:

Ponds west flowing drainage

150 m thick sedimentary section

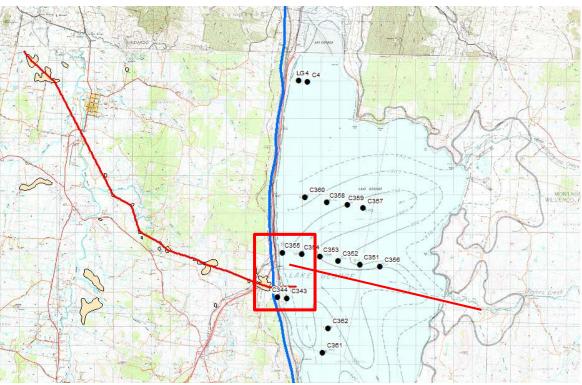

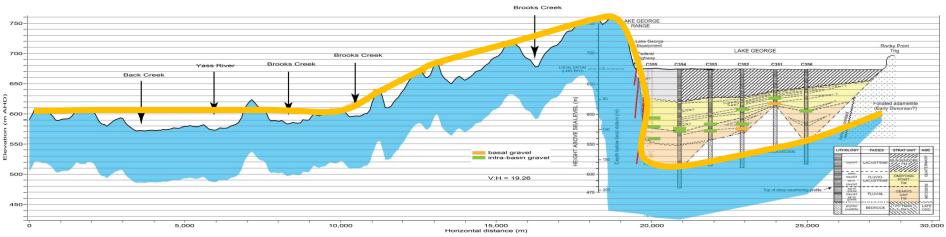

10.0100

GEOSCIENCE AUSTRALIA

Basin <*ca.* 4 Myr

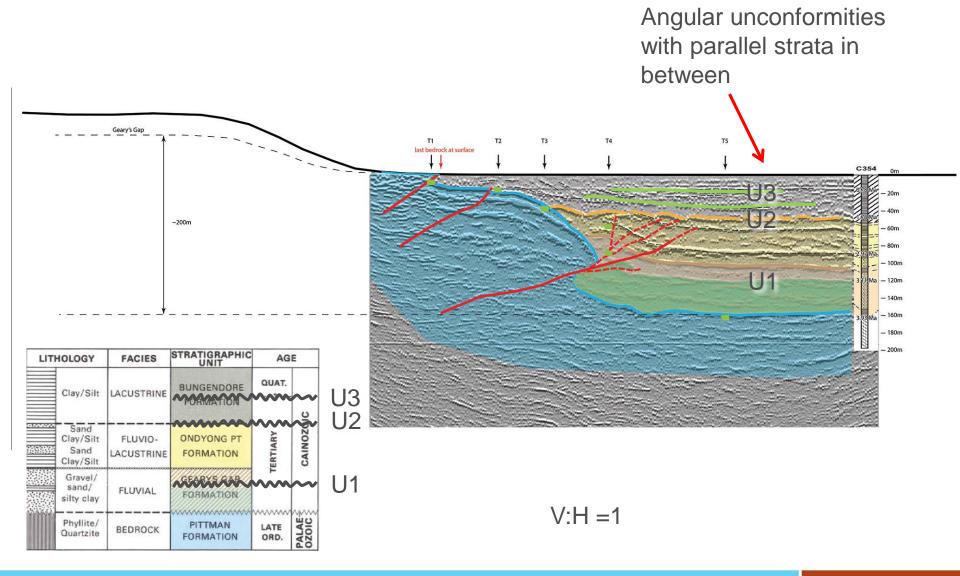

- Paleo-channel gravels extend from basin onto the hanging wall
- 250 m of <ca. 4 Myr vertical separation

GEOSCIENCE AUSTRALIA

Shallow seismic reflection data and interpretation

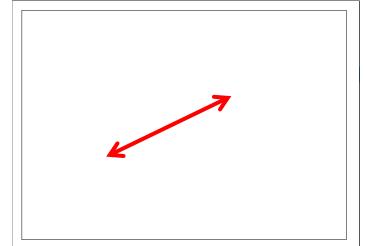

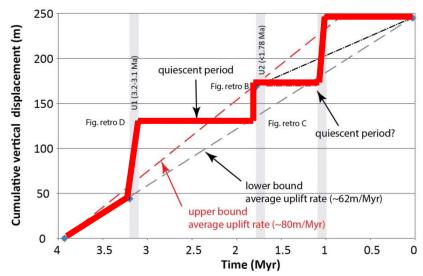

GEOSCIENCE AUSTRALIA

© Commonwealth of Australia (Geoscience Australia) 2016

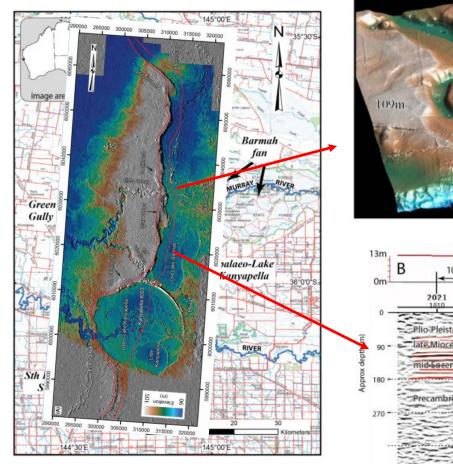

Contributions to seismic hazard understanding

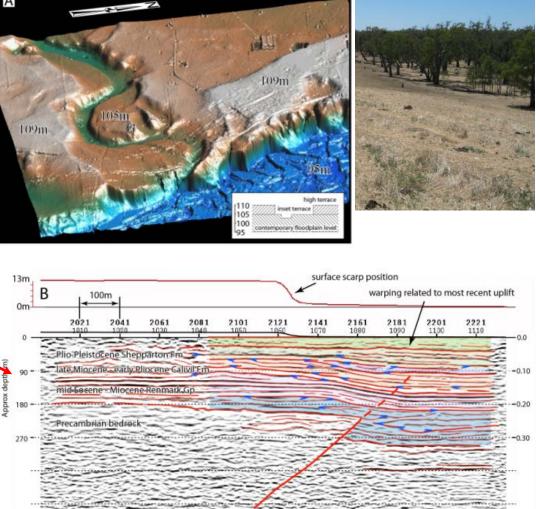

- Characteristic magnitude
 - 75 km long fault
 ~ Mw7.4
 60-80 m/Myr uplift rate
 <25km from Canberra
- Episodic recurrence
 - ~0.78 1.3 Myr quiescent periods separating active periods involving 40-70 m of uplift
 - Recurrence in an active period not yet known

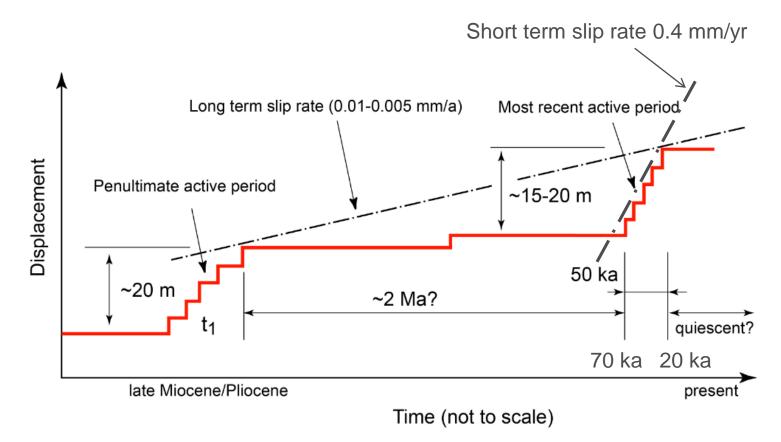

Recurrence in an active period? the Cadell scarp, NSW/Victoria

GEOSCIENCE AUSTRALIA

Clustered Cadell Fault rupture behaviour

Clark et al. (2015) GSL Special Publication doi: 10.1144/SP432.2

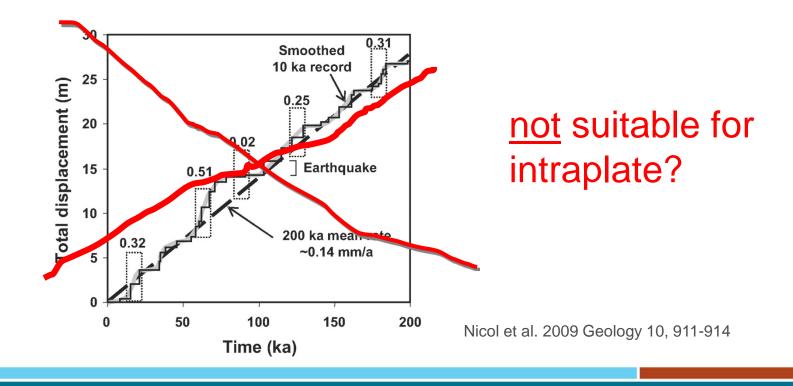

Short term slip rate 400 m/Myr! Recurrence for M7.4 ~ 8kyr on average

GEOSCIENCE AUSTRALIA

Plate margin recurrence/slip model

- Fairly regular build up of elastic strain and release as earthquakes
- Long term slip rates provide a reasonable estimate of activity at shorter time frames (i.e. for seismic hazard purposes)

Random recurrence?

Random distribution of 15 events

For example number of M7 earthquakes in 100,000 years Could very easily be interpreted as Episodic or Periodic or Random

Care is needed when inferring a pattern

Figure 9.30: Visualization of the effect of the aperiodicity parameter η on the recurrence of earthquakes. Each row represents an earthquake history with time increasing to the right. The short vertical lines in each row represent 50 characteristic earthquakes drawn from a Weibull distribution of identical mean recurrence time, but with the aperiodicity parameter (equivalent to the coefficient of variation) increasing from 0 (top row) to 2.2 (bottom row). An aperiodicity of 0.0 represents perfectly periodic recurrence. As the aperiodicity parameter increases, the time series become less regular and more aperiodic or "temporally clustered." The gray rectangle represents an arbitrary time window that captures five earthquakes on average (about 10% of the earthquake history), and represents a typical detailed paleoseismic field study. Note that this short time window can be representative of the entire earthquake history, or unrepresentative, or somewhere in-between. Adapted from Ward (1992).

Omori's Law? (Liu et al. 2016, Calais et al. 2016)

Long lived 'stress pool': strain accumulation and release rates disparate.

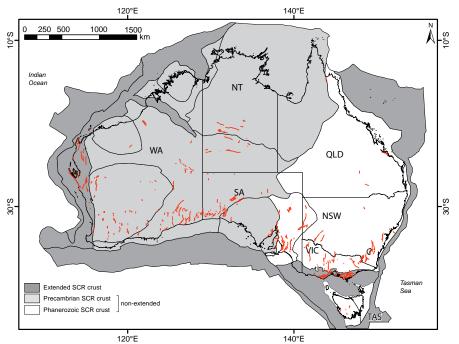

GEOSCIENCE AUSTRALIA

Fault displacement hazard: summary

CRATONIC (Archaean and non-reactivated Proterozoic): N/A?

- often complex rupture geometry and trace complexity
- recurrence not in a meaningful time frame for hazard?
- NON CRATONIC and EXTENDED
- little known about rupture geometry and trace complexity
- potential for recurrence
- recurrence in an active period drives hazard

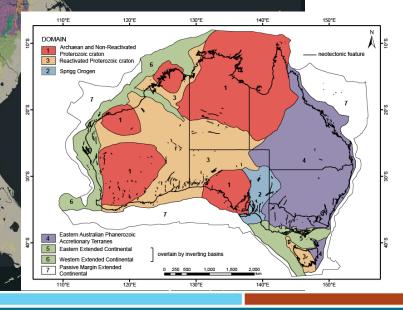

Global Crustal Analogues

Archaean and Proterozoic core of Nth America similar to nonextended cratonic (Precambrian) SCR crust

Phanerozoic foldbelts (incl. Cheraw/Meers faults) similar to nonextended non-cratonic SCR crust

Passive margins (Charleston source zone) and aulacogens (Reelfoot, Sth Oklahoma, Ottawa, Saguenay, Charlevoix) similar to elements of extended non-cratonic SCR crust
